# **Supervisor Mode Instructions:**

Instruction	rd	rs1	rs2	cr	imm	Notes
sb/h/w.r		rs1	rs2	-	imm	"store raw", allows stores at any point in memory. Uses rs1 as base-ptr
lb/bu/h/hu/w.r	rd	rs1		-		"Load raw", same as store raw
dtp	rd	rs1		-		"data to pointer", creates a pointer from data
ptd	rd	rs1		-		"pointer to data", extracts base address of pointer as data
itd	rd	rs1		-		"index to data", extracts index of pointer as data

#### **DOKUMENTATION: ELF-FILES**

"Executable and Linkable Format"-Files bestehen mindestens aus einem Header, einer "Program Header Table" und einer "Section Header Table". Im Header werden Informationen über das ELF-File selbst gespeichert, wie z.B. die Prozessorarchitektur, für welche das Programm kompiliert wurde und die Positionen der PHT und der SHT in Relation zum File-Anfang. In einem Program Header werden Informationen gespeichert, die dem Betriebssystem angeben, wie viele und welche Arten von virtuellen Seiten für dieses Programm benötigt werden. In einem Section Header wird angegeben, in welche Einzelteile das Programm zerlegt wurde und ob noch mehr Informationen über das Programm im ELF-File zu finden sind (z.B. für relocatable Programme).

#### Daten

Statische Daten werden von einem Compiler über Assemblerdirektiven immer so in die .data bzw. .rodata Sektionen abgelegt, sodass sie in der Symboltabelle des ELF-Files immer als Objekt mit seiner Größe eindeutig erkennbar sind.

```
static char stringA[] = "hello world!";
                                                                static const char stringB[] = "hello world!";
         stringA, @object
.asciz "hello world!"
                                                                         stringB, @object
.asciz "hello world!"
stringA: .asciz
                                                               stringB: .asciz
          stringA, .-stringA
                                                                          stringB, .-stringB

//Symbol Table im erzeugten ELF-File
Symbol table '.symtab' contains 60 entries:
                                    Bind
   Num: Value
                     Size Type
                                                      Ndx Name
    49: 00000000
                       13 OBJECT LOCAL
                                          DEFAULT
                                                       5 stringA
    50: 00000000
                       13 OBJECT LOCAL
                                          DEFAULT
                                                       6 stringB
```

Ein Zugriff auf solche statischen Daten kann in executables und muss in relocatables über die Global Offset Table (GOT) stattfinden. Angenommen ein Programm läge an der physikalischen Adresse 0x0 und seine zugehörige GOT an der Adresse 0x1000 und am Offset 8 der GOT stünde die Adresse für das Symbol stringA, dann würde mit folgenden Assembly befehlen auf diesen Eintrag zugegriffen werden.

```
auipc t2, 0x1 # R_RISCV_GOT_HI20 (symbol), R_RISCV_RELAX
lw t2, 8(t2) # R_RISCV_PCREL_LO12_I (auipc), R_RISCV_RELAX
```

In einer executable können die Immediates für diese Befehlssequenz direkt befüllt werden, da der Abstand des Programms zur GOT schon beim Kompilieren des Programms bekannt ist. Bei einem relocatable Programm belässt der Compiler diese Immediates mit 0 und markiert die Befehle in der "Relocation Section" als unaufgelöst. Sowohl die GOT als auch die .data oder .rodata Sektionen können vom Betriebssystem beim Laden des Programms an beliebige Stellen im Speicher platziert werden. Sind alle Sektionen platziert, kann der Dynamische Linker anhand der Tags der Einträge in der Relocation Section herausfinden, wie er die Immediates für die aufzulösenden Symbole zu berechnen hat. R\_RISCV\_GOT\_HI20 z.B. bedeutet, dass für diese Instruktion die obersten 20 Bits der Differenz aus Position der Instruktion und Position der GOT benötigt. Die Relax Tags sollen anzeigen, dass es je nach Positionierung möglich sein könnte, eine der beiden Instruktionen zu sparen falls z.B. Instruktion und GOT nah genug beieinander liegen.
